ACKNOWLEDGMENTS

Billy Glenn, Pam Roy, and Chantalle Brunson put in many tedious hours of interviewing fishermen. The staffs of QuanTech, Burke Marketing Research, and the Washington, D.C. office of the National Marine Fisheries Service provided assistance in various aspects of the project. Part of this work was conducted in cooperation with the Department of the Interior, U.S. Fish and Wildife Service and funded in part ( $75 \%$ of total costs) by the Federal Aid in Sport Fish Restoration Act (16 U.S.C. 777-777K).

The South Carolina Department of Natural Resources prohibits discrimination on the basis of race, color, sex, national origin, handicap, or age. Direct all inquiries to the Office of Personnel, P.O. Box 167, Columbia, SC 29202.

## INTRODUCTION

The Fisheries Statistics Program (FSP) of the Marine Resources Division (MRD) is responsible for the collection, compilation, analysis, and distribution of fishery-dependent data for South Carolina's marine fisheries. One instrument used to obtain such information for recreational finfish fisheries is the Marine Recreational Fishery Statistics Survey (MRFSS) conducted annually in cooperation with the National Marine Fisheries Service (NMFS). This is a generalized survey with the principal objectives of obtaining participation, effort, and catch data on a regional basis.

In 1994, the MRFSS was conducted during March through December. A telephone poll of coastal households by Burke Marketing Research obtained information on participation and effort. An on-site intercept survey or creel census was administered by QuanTech, which contracted the field work to the FSP. Fishermen interviewed included those fishing from shore or manmade shore facilities (docks, piers, bridges), charterboats, and private boats. Headboat fishermen were not included. Fishermen using gear other than hook and line were rarely intercepted and the results of the MRFSS therefore did not pertain to such activities as gill netting, gigging, and spearfishing by divers.

Additional catch and effort data for the private boat mode were collected in a State Finfish Survey. This effort was primarily targeted at fishermen fishing in estuarine areas.

Since July, 1992, private boat anglers have been required to have a marine fishing stamp, but not shore anglers and charterboat passengers. Operators of piers and charterboats obtained permits from the Department of Natural Resources and submitted monthly reports of daily fishing activity to the FSP. Pier operators reported daily attendance, while charterboat captains reported numbers of anglers, hours fished, and catch (numbers by species kept and released) per trip. Headboat operators were required by federal regulations to submit similar reports to the NMFS.

## METHODOLOGY

MRFSS procedures for the telephone and intercept surveys were described by Essig et al. (1991) and Van Voorhees et al. (1992). In 1993, the NMFS revised procedures for processing telephone survey data used to estimate effort. These included 1) different guidelines for treatment of proxy data, 2) imputation for missing data, and 3) adjustment of fishing effort data by county for county population. The resulting effort estimates were statistically more reliable than those derived previously and, in South Carolina, were usually higher. The catch estimates derived from the effort data also generally increased when the new procedures were applied.

Early in 1995, the NMFS issued revised historical data sets based on the new calculation methodology. The new estimates generated from these data are contained in this report and are the basis for trend analysis, etc.

Fundamental field procedures for the intercept survey have remained basically unchanged since 1987, the first year of recent MRD participation. Minor modifications have been made to the annual questionnaires. The sampling schedule, provided by QuanTech, was based on historical usage patterns by fishing mode and sampling wave. Sampling waves were two-month intervals beginning with March-April. Site assignments reflected relative usage rates with the most heavily trafficed locations receiving selection priority.

On a scheduled sampling day, the creel clerk proceeded to the assigned site. If the clerk determined that the assigned location would be unproductive, he/she then went to the nearest alternative location for that mode. The clerk usually remained on-site until the day's MRFSS quota ( 30 interviews) was obtained or further effort appeared unwarranted. SFS sampling followed similar procedures, although selection of alternate sites was left completely to the discretion of the creel clerk.

FSP staff obtained MRFSS interviews at 25 shore sites, 8 charterboat docks, and 25 public boat ramps or landings (Table 1). SFS data were collected at 25 sites as indicated in Table 2. Although these visits were scheduled by the FSP, their distribution was largely determined by MRFSS assignments because of logistical considerations.

MRFSS interviews were conducted in accordance with procedures and guidelines established by the NMFS and QuanTech. An MRFSS interview pertained to an individual fisherman with all memebers of a fishing party usually being interviewed (there were exceptions, particularly with charterboat groups). An SFS interview was a trip interview and often included more than one angler.

Information obtained included the number of anglers in the party, hours spent fishing, area fished, targeted species, and residency of the respondent. Catch data consisted of the numbers of fish caught by species and their disposition (i.e., retained, discarded dead, released alive, given away, or used for bait). Up to 20 fish of each species were weighed and/or measured per catch.

FSP staff coded and edited MRFSS interview forms and forwarded them to QuanTech for additional processing. QuanTech provided summaries of intercept survey wave data and Burke Marketing Research furnished compilations of information from the phone surveys. The NMFS provided estimates of participation and effort. The NMFS also supplied estimates of the total numbers of fish caught by species and wave based on expansions of creel census catch rate data and total numbers of trips.

All data from the SFS were processed by the FSP. The FSP also calculated estimates of catch per unit of effort (CPUE) for species of interest, using data from both the MRFSS and SFS. CPUE was calculated by adding the total number of fish caught on targeted trips and dividing this figure by the total number of anglers on those trips. A targeted trip was one in which the species was either identified as the species preference or at least one was caught.

In cases where catches were pooled for a fishing party, e.g. a charterboat group, and anglers couldn't recall how many fish each had caught, the group catch was divided by the number of fishermen to obtain CPUE. It should be emphasized that the numbers and kinds of fish not inspected by the creel clerks (e.g. released or discarded catch) could not be verified.

RESULTS
Essig et al. (1991) described considerations pertinent to interpretation of results from the MRFSS, e.g. sources of variation and their implications, potential elements of bias, and possible effects of data adjustments. Most of these applied to the South Carolina survey results and are mentioned where appropriate.

## Survey Logistics

The telephone survey contacted 7,139 eligible households during waves 2-6 (March-December). In the MRFSS creel census, QuanTech accepted 1,836 interviews.

Charterboat anglers represented $15 \%$ of the creel census sample population, shore anglers $39 \%$, and private boat fishermen $46 \%$. About $62 \%$ of the charterboat sample came from Beaufort County, 22\% from Charleston County, and 18\% from Georgetown County. Fishermen on the Grand Strand (Horry County) piers represented 57\% of the shore mode group. The distribution of the private boat sample by county was 39\% Georgetown County, 34\% Beaufort County, and 25\% Charleston County.

Distribution of the MRFSS interviews by fishing area, wave, and mode is shown in Table 3. About 61\% of the shore fishermen interviewed were fishing in the ocean (mostly from the Grand Strand piers) with $39 \%$ fishing in inland waters. About $28 \%$ of the charterboat anglers had been fishing in inland areas, $17 \%$ in coastal ocean waters, and the remaining $55 \%$ offshore. The vast majority ( $88 \%$ ) of the private boat fishermen had been fishing inland waters. About $8 \%$ had fished offshore and $4 \%$ in coastal ocean areas.

Allocation of survey effort and costs is summarized in Table 4. MRFSS and SFS interviews were not directly additive, since the SFS interviews were primarily group interviews ( 2 X would be a reasonable conversion factor to individual interviews).

## Participation

Nine percent of the coastal households contacted during the MRFSS phone survey contained a member who had gone salt water sport fishing during the last two months. At least one member had gone salt water sport fishing during the past year in 18.4\% of all eligible households. Table 5 lists the positive response rates per wave compared with those from previous years.

Coastal residents comprised the majority ( $52 \%$ ) of the anglers interviewed in the MRFSS (Table 6). They were the predominant group in the private boat ( $72 \%$ ) and shore ( $47 \%$ ) modes. Out of state residents represented $34 \%$ of the total sample population and the vast majority ( $83 \%$ ) of the charterboat fishermen.

During July through December, 1994, a total of 73,095 salt water fishing stamps was sold to private boat anglers. Sixpassenger charterboat permits were acquired by 137 individuals (= number of boats) with 25 permits issued to vessels (mostly headboats) with larger passenger capacities. Nine fishing piers obtained permits.

Total participation was estimated at 859,000 fishermen. Coastal residents $(457,000)$ comprised the largest group (53\%). Out of state anglers $(247,000)$ represented $29 \%$ and noncoastal residents $18 \%$.

## Effort

Total effort was estimated at 1.908 M trips, distributed by wave, mode, and residential category as indicated in Table 7 . Coastal residents contributed 59\% of the effort, out of state anglers $27 \%$, and noncoastal residents $14 \%$. Distribution of effort by mode and fishing area is shown in Table 8.

Respondents in the phone survey were asked to specify the number of trips made in each mode. About $62 \%$ of the total trips reported had been made in the private boat mode with $35 \%$ being shore trips. About $3 \%$ of the total effort consisted of charterboat trips with only $0.3 \%$ having been headboat trips.

The average numbers of trips (= days fished) made per angler in each wave and mode as reported in the phone survey are indicated in Table 9. The annual figures are based on wave 6 responses to the question, "how many days did you fish in the last twelve months?" as a proxy for the year's total effort.

The time of day of fishing as reported in the phone survey is shown in Table 10. The distribution of creel census interviews is shown for comparison. About $10 \%$ of the trips reported in the phone survey were made between midnight and noon, when there was no onsite sampling. About 38\% occurred after 6:00 PM, whereas only 1\% of the on-site interviews was conducted then.

Table 11. Number of private boat trips by type of access (from phone survey). Source: Burke Marketing Research.

Respondents to the phone survey were asked whether they had used public access points or private facilities on their private boat trips. Distribution by point of origin is shown in Table 11. About $76 \%$ of the trips originated from public locations. Public launching ramps were the most commonly used type of access, accounting for $60 \%$ of all private boat fishing trips.

## Species Preferences

Most of the shore fishermen expressed no species preference. Spot was the most popular target of shore fishermen, particularly those fishing from the ocean piers.

Species preferences of charterboat anglers were determined from mandatory trip reports submitted to the FSP. Table 12 lists the results. One-third of the inland anglers identified sharks as their target. The next most popular species was red drum, specified by $15 \%$. About $32 \%$ of the inland charterboat fishermen indicated no species preference.

In coastal waters, sharks were the predominant target, sought by roughly half of the fishermen. Spanish mackerel and tarpon were the next most preferred species. About $10 \%$ of the coastal charterboat anglers expressed no species preference.

Mackerels were the primary targets of offshore charterboat anglers with $39 \%$ seeking king mackerel and $12 \%$ targeting Spanish mackerel. About $32 \%$ of the offshore anglers indicated no species preference with most engaged in surface trolling.

Preferences indicated by private boat anglers in both surveys were similar and the data were combined in Table 13. Red drum and spotted seatrout were the most popular choices in inland areas, being specified by $24 \%$ and $19 \%$ of all fishermen interviewed, respectively. Flounders were the third choice, identified by $14 \%$ of the inland private boat anglers. No other species exceeded $5 \%$. About $28 \%$ indicated no species preference.

The majority of the private boat ocean fishermen were interviewed at the Murrells Inlet ramp in Georgetown county. In coastal ocean waters, flounders were the most preferred species ( $17 \%$ of those fishermen interviewed). Spanish mackerel and spot each had $11 \%$ and red drum 8\%. About $35 \%$ of the fishermen indicated no species preference. Offshore fishermen primarily targeted king mackerel ( $37 \%$ of those anglers interviewed) with black sea bass the second choice ( $14 \%$ ). About $25 \%$ of the offshore fishermen had no preference.

## Catch

MRFSS catch estimates are vulnerable to large sampling errors associated with the numbers of fishermen interviewed and catches inspected (sample size), the range in numbers of fish in individual

catches (variability), and the frequency of occurrence of unusually large or small catches (probability distribution).

Misidentification and confusion over common names can cause substantial errors in the estimated landings of similar species when the creel clerks are unable to inspect the catches. For species having large percentages of the catch unavailable for such inspection, the estimated total landings can be highly inaccurate. For the most frequently caught species, relative ranking and trends in catch appear to be reasonably reliable: however, caution should be exercised in quantitative applications of the absolute numbers.

The estimated total catch of marine fish was 7.886 M fish. Disposition is shown in Table 14. Landings by wave are listed in Table 15. Distribution by fishing area is indicated in Table 16. The numbers for some species, particularly pinfishes, were extremely high by historical standards and were probably greatly exaggerated.

Oceanic pelagics comprised a very small part of the overall landings. Dolphin was the principal species. Most of the catch was accounted for by charterboat fishermen.

Landings of reef fish consisted predominantly of black sea bass. Much of this catch, particularly in inland waters, consisted of very small sea bass which were released. The high estimate for spottail pinfish was probably attributable to sampling error. No landings were reported for red porgy and vermilion snapper, although charterboat reports submitted to the MRD listed both species.

Spanish mackerel and bluefish dominated catches of coastal pelagic species, particularly in the nearshore ocean (< 3 mi .) zone. Relatively large percentages of the catch of both species were released with the majority of bluefish being < 2 pounds. Pier fishermen contributed substantially to the landings of both species.

Most of the inshore sportfish catch was taken by private boat anglers with red drum and spotted seatrout the principal components. Relatively high percentages of the landings of both species were released ( $75 \%$ for red drum and $66 \%$ for spotted seatrout). The flounder catch consisted mostly of southern flounder; at least 75\% of the unclassified landings (mostly released) probably consisted of this species.

Inshore bottomfish, particularly spot, were the principal target of shore fishermen and the major part of their catch. Kingfishes and spot were usually targeted with croaker an incidental catch.

Identification of sharks was questionable, since so many were released. Small species such as sharpnose and bonnethead appeared

$\begin{array}{ll}7 & 4\end{array}$
to be the major catch components, although blacktips were commonly cited by boat anglers in coastal waters.

## Shore Mode

The majority of the anglers interviewed were fishing off the Grand Strand piers or inland bridges and docks. Very few bank or surf fishermen were intercepted. Although most of the piers operated 24 hours a day during the season, there was no night sampling.

Pier operators reported a total attendance of 204,113 anglers. Six of the piers exceeded 20,000 fishermen in annual attendance. The peak season was July-September (91,542 anglers), followed by the fall (October-December) with 59,321 fishermen. Most of the facilities were closed during January and February.

The total estimated shore catch (Table 17) largely reflected what was caught on the Grand Strand beachfront piers. Principal species included inshore bottomfish, Spanish mackerel, bluefish, and sharks. The fall run of spot was the major attraction for the piers with over half of the annual shore catch of this species landed during wave 6 . Spanish mackerel and bluefish were significant in the summer.

## Charterboat Mode

This discussion is based on data submitted by operators under the state's mandatory reporting system. The appendix contains a comparison of these results with those from the MRFSS and evaluation of the reliability of the two data sets.

During calendar year 1994, 175 vessels (excluding those designated as headboats by the NMFS) were permitted for at least one month. Distribution of the fleet by length and port location was as follows:

|  | Length (ft) |  |  |  |  |
| :--- | ---: | ---: | ---: | :---: | ---: |
| Beaufort County/GA. | 20 | $20-26$ | $27-31$ | $32-40$ | $>40$ |
| Charleston county | 11 | 24 | 6 | 15 | 5 |
| Georgetown County | 0 | 15 | 8 | 10 | 20 |
| Horry County/N.C. | 1 | 6 | 6 | 8 | 6 |

Length and/or location were unknown for five vessels.
A total of 147 boats reported making at least one trip in 1994, carrying 26,175 anglers. Participation by season and fishing area is shown in Table 18. operators reported 5,951 trips, distributed by length category and port location as follows:

Vessels for which length and/or port location were unknown made seven trips. Table 19 lists the distribution of trips by fishing area and season.

About $21 \%$ of the boat trips were made in inland areas, $21 \%$ in coastal ocean waters, and $58 \%$ offshore. Artificial reef trips accounted for $14 \%$ of the total ocean effort.

Roughly one-third of the annual effort in inland areas was not targeted at any particular species (Table 20). Sharks were the most popular targeted group in terms of directed effort, followed closely by red drum. Appreciable seasonal effort was also directed at spotted seatrout and tarpon.

In coastal ocean natural bottom areas, sharks were the dominant target group. over manmade habitat, sheepshead and king mackerel were the principal species preferences.

In the offshore ocean zone, about $37 \%$ of the boat hours over natural bottom were not directed at any particular species. King mackerel was the overwhelming choice of trollers, followed by Spanish mackerel, while groupers were the most preferred target of bottom fishermen.

King mackerel was also the dominant preference of anglers trolling over offshore artificial reefs, followed again by Spanish mackerel. Very little effort was directed at bottomfish.

About $30 \%$ of the total ocean effort was not targeted at any particular species and consisted of surface trolling. About $30 \%$ was directed at king mackerel. About $80 \%$ of the directed king mackerel effort occurred over offshore natural bottom and $16 \%$ over offshore artificial reefs.

Sharks were the second most targeted group by ocean fishermen (about $10 \%$ of the total boat hours). Nearly all of the directed shark fishing consisted of bottom fishing over coastal natural bottom.

Eight percent of the overall ocean effort was directed at Spanish mackerel. About 55\% of the directed Spanish mackerel fishing took place over offshore natural bottom, $20 \%$ over coastal natural bottom, and $20 \%$ over offshore artificial reefs.

About $70 \%$ of the total ocean effort as measured in boat hours occurred over offshore natural bottom. Coastal natural bottom

Table 20. Directed 1994 charterboat effort in South Carolina, as reported on daily logsheets. Inland effort is in angler hours, ocean effort is in boat hours.

supported $19 \%$ with offshore artificial reefs accounting for $9 \%$.
Charterboat landings as reported to the FSP by vessel operators are listed in Table 21.

Aggregate charterboat landings of oceanic pelagic species were slightly below those in 1993 with minor decreases for nearly all species except wahoo. Only 76 billfish were reported compared to 98 in 1993. Most of this decline was attributable to blue marlin. The spring (April-June) quarter was the peak season. Landings for the principal species, dolphin, were higher in both April and June in 1994, but there was a large decrease in the May landings. Inclement weather was probably a significant detractive factor. The total dolphin catch in numbers of fish was down about $2 \%$, while landed weight increased $17 \%$ due to the unusually large average size in 1994.

Total numerical landings of the principal reef fish species, black sea bass, increased $21 \%$ over the 1993 figure. Numbers of most other species were also up moderately with the aggregate grouper catch 12\% larger.

Landings of king mackerel were down $22 \%$ from those in 1993. The number of fish caught per boat hour of trolling, while following the same seasonal pattern as in previous years, was consistently lower (Fig. 1). The total Spanish mackerel catch was about the same as in 1993. Monthly catch rates over natural bottom were consistently lower in 1994, while those over artificial reefs were generally higher than in 1993. Overall CPUE was somewhat lower.

Spanish Mackerel

| SEP | 503 | 136 | 3.70 | 152 | 29 | 5.24 | 3.97 |  |  |
| Total | 3,999 | $\mathbf{1 , 2 1 2}$ | $\mathbf{3 . 3 0}$ | $\mathbf{1 , 6 5 4}$ | 408 | 4.05 | $\mathbf{3 . 4 9}$ |  |  |

The overall number of red drum reported caught in 1994 was 27\% greater than the 1993 catch with more effort directed at this species. Much of the catch consisted of large fish that were released. The total catch of spotted seatrout, in contrast, declined 43\%. There was much more directed effort for tarpon in 1994 and the catch (nearly all released) increased substantially.

Shark species identities are confusing and the species composition of the reported landings was therefore questionable. The principal components appeared to be sharpnose and blacktips. The overall number of sharks reported caught increased 45\% from 1993 with the majority released.

## Private Boat Mode

Estimated landings by private boat fishermen are listed in Table 22.

Very few of the private boat anglers intercepted in the MRFSS had been fishing in the Gulf Stream or farther offshore, so few landings of oceanic pelagic species were documented.

Most of the reef fish catch was accounted for by private boat anglers with black sea bass the only significant component. The large landings of spottail pinfish appeared to be due to sampling error.

Private boat anglers caught about 43\% of the estimated king mackerel catch and $26 \%$ of the overall Spanish mackerel landings. King catches were spread throughout the year with Spanish mackerel landings almost entirely during July and August. Most of the bluefish catch was taken incidentally while fishing for other species.

The principal species sought by private boat anglers were red drum, spotted seatrout, and flounders. Most of the red drum landings and all of the spotted seatrout catch were attributable to this mode, primarily in late summer and fall. Flounder landings peaked in late spring and early summer, while sheepshead were taken mainly in early spring. Private boat anglers also landed appreciable numbers of sharks during the summer and inshore bottomfish in the fall.

Data from the MRFSS and SFS were used to calculate CPUE indices for major species of interest. Input data for red drum, spotted seatrout, flounders (mostly southern), and sheepshead are provided in Tables $23,24,25$, and 26 , respectively.

The MRFSS contributed $38 \%$ of the total sample used to derive CPUE for red drum. Indices of fishing success were generally similar for data from both surveys. CPUE was highest in Beaufort County and declined northward.

MRFSS data represented $36 \%$ of the sample for spotted seatrout. CPUE indices determined from both survey data sets were similar except in Georgetown County, where both sample sizes were very small. CPUE was highest in the central part of the coastline.

The MRFSS contributed 57\% of the flounder observations. Variability between areas and surveys was higher than with the other species, although results from each dataset were comparable in the Georgetown/Horry County area, where most of the directed activity occurred. Combined indices were similar there and in Beaufort County with success considerably less in the central coastal area.

| Fish/angler hour | 0.29 | 0.40 | 0.36 |
| \% of anglers with no fish | 45 | 38 | 40 |

The sample sizes for sheepshead were small and were pooled into a single dataset for the entire coastal area. Anglers intercepted in the SFS appeared to have been somewhat more successful than those interviewed in the MRFSS.

## Length Distribution

A total of 311 red drum was measured with 93 from the MRFSS and 218 from the SFS. Length distributions by county are shown in Fig. 2. Average size increased from south to north; in Beaufort County, it was 42.2 cm , in charleston County 43.9 cm , and in Georgetown County 47.5 cm . The average total length statewide was 43.2 cm (Fig. 3), Because of the 27 in . ( 69 cm ) maximum size limit, large fish had to be released.

A total of 367 spotted seatrout was measured with the sample divided roughly evenly between Beaufort and Charleston Counties. Very few fish were observed in Georgetown County. Most of the sample was obtained during wave 5 . Length distribution by county is illustrated in Fig. 4. There was little difference in average size between Beaufort ( 36.7 cm ) and Charleston Counties ( 36.9 cm ). The average size statewide was 36.9 (Fig. 5).

The total sample size for southern flounder ( $\mathrm{N}=238$ ) was relatively large compared to previous years and somewhat more evenly distributed geographically. The statewide average total length was 39.5 cm . Length distribution is shown in Fig. 6.

Sheepshead were distributed over a wide size range (Fig. 7). Fish taken in the ocean were generally larger than those from inland waters.

Sample sizes for other important species were smaller than in recent years. Length distributions and mean sizes are listed in Table 27.

## DISCUSSION

Discrepancies between results from the MRFSS charterboat sampling and MRD reporting system are discussed in the Appendix.

## Survey Logistics

Geographical distribution of the MRFSS interviews within modes differed from that in recent years. The percentage of shore anglers interviewed who fished from the Grand Strand piers was much higher than in 1993 and close to the historical average. This reflected the return to normal operation of all facilities and addition of one new pier.

Prior to 1993, most charterboat interviews were obtained in Murrells Inlet. In 1994, 60\% of the sample was taken in Beaufort County, 22\% in Charleston County, and 18\% in Georgetown County.

According to MRD reports, $54 \%$ of the boat trips originated in Beaufort County, 23\% in Charleston County, and 8\% in Georgetown County. The remainder took place in Horry County. In the last two years, the distribution of the sample population has reflected the distribution of actual effort much more representatively than previously.

Geographic distribution of interviews in the private boat mode was more even between counties than in 1993. In 1993, less than 15\% of the sample was obtained in Beaufort County, whereas in 1994 the contribution was $34 \%$. The number of sites contributing more than 20 interviews also increased, although Murrells Inlet remained by far the major source of interviews ( $35 \%$ of the mode total).

## Participation and Effort

Estimated participation was the highest recorded to date. The annual trend is shown in Fig. 8 (headboat anglers not included). The indicated increase from 1993's level appears highly improbable.

The estimated number of coastal resident anglers increased from 139,000 to 457,000 , according to the MRFSS. The number of marine stamps issued to private boat fishermen was practically identical (about 73,000 ) in both years. The percentage of coastal households containing a saltwater angler was $18.4 \%$ in 1994 vs $18.0 \%$ in 1993, hardly sufficient to account for the indicated increase. The positive responses per wave were comparable in both years (except for wave 5) as well.

In contrast, the estimated number of out of state anglers declined from 306,000 in 1993 to 247,000 . MRD reports indicated increases in pier attendance and charterboat passengers, both categories largely composed of out of state residents.

Estimated effort also was the highest to date (Fig. 9, which does not include headboat trips). Shore effort increased about $9 \%$. This appears conservative given that reported pier attendance increased $31 \%$. The MRFSS phone survey results reported that average trips per angler in the shore mode increased from 11 in 1993 to 16 in 1994, a $45 \%$ increase.

The MRFSS estimates included no charterboat effort for waves 2, 4, and 6, yet the mode estimate was still more than double the number of angler trips reported to the MRD. Charterboat effort reported to the MRD increased about $13 \%$. The phone survey results indicated an increase in average trips per year from 0.43 to 0.57 .

The estimated private boat effort increased $28 \%$ with major increases during each wave except 4 and 6 . The indicated decrease (7\%) in wave 6 effort was probably underestimated. The weather then was so bad that we were unable to make interview quotas with half of the MRFSS assignments rained out. The phone survey results suggested that average effort per angler declined from 35.95 trips

Fig. 8. Estimated participation in the South Carolina recreational hook and line fishery.

Page 1

Fig. 9. Estimated effort in the South Carolina recreational hook and line fishery.

Page 1
per year in 1993 to 29.89 in 1994. The large increase in estimated overall private boat effort probably reflects the unrealistically large increase shown for coastal resident participants.

## Catch and Catch Rates

Estimated total landings of oceanic pelagics, particularly dolphin, were very low compared to those in 1993. This obviously reflected the absence of reported charterboat catches during waves 2 and 4. Charterboat landings of this group reported to the MRD were only slightly less than those reported in 1993 with the dolphin catch down just $2 \%$ in numbers of fish.

With the exception of black sea bass, estimated landings of major reef fish species were much lower than in 1993. Again, the missing wave data for the charterboat fishery were a contributing factor. MRD charterboat reports indicated moderate increases in the 1994 landings for most species, including red porgy and vermilion snapper. These species weren't reported, according to the MRFSS data.

King mackerel landings appeared to decline substantially from those in the last two years, according to all information sources. The low MRFSS figure obviously reflected the absence of three waves of charterboat landings. Numbers of fish caught by charterboats as reported to the MRD were $22 \%$ less than in 1993 and CPUE was consistently lower throughout the season. Commercial landings were also down appreciably during the peak summer recreational season.

Estimated Spanish mackerel landings tripled. This probably was attributable to sampling error. An unusually high percentage of the catch was reported released (and could not be verified), 69\% compared to the typical $15 \%$ in 1993. The retained catch as estimated by the NMFS increased by only $10 \%$. Charterboat landings reported to the MRD were about the same as in 1993 with CPUE somewhat lower.

Inshore sportfish landings increased for the principal species. Estimated red drum landings were high by historical standards and substantially above those in recent years (Fig. 10). The percentage of released fish (75\%) was exceptionally high, however, and may have inflated the estimates excessively: these landings could not be verified. The estimated retained catch was about 10\% less than that in 1993. CPUEs calculated from data from both surveys were comparable and the statewide index (Table 28) was relatively high. Statewide CPUE was 86\% higher than in 1993 compared to an overall estimated catch that was $64 \%$ higher.

The estimated catch of spotted seatrout was also relatively large by recent standards (Fig. 11). Again, the percentage of released fish was abnormally high with the retained catch only $54 \%$ of that estimated in 1993. CPUE indices suggested that the total catch may have been overestimated. The Charleston County index was

Fig. 11. Estimated recreational catch of spotted seatrout.

Page 1
relatively high, but those for other areas were lower than in recent years. Inclement weather during wave 6 probably contributed to reduced landings. Most of the catch was reported during wave 5 , in contrast to normal years when the principal landings occur in wave 6 .

The catch of southern flounder appeared to be considerably higher than in 1993. The CPUE was substantially greater in Georgetown County, where most of the directed effort was observed.

The estimated catch of sheepshead declined $36 \%$ from that in 1993. This decline appeared realistic, given that statewide CPUE was 44\% lower.

## Length Distribution

Mean lengths and size distributions of the principal recreational species continued to be consistent with those observed in recent years (Table 29). The maximum size limit probably depressed the average size of red drum slightly, since anglers reported releasing many fish over the 27 in ( 69 cm ) maximum legal size that could have been retained in previous years.

## APPENDIX I

Since July, 1992, state law has required all charterboat operators to obtain a permit and submit monthly reports of daily fishing activity to the MRD. These reports are completed for each trip and include the number of anglers, hours fished, number of fish caught by species, number released by species, and pounds retained by species.

During 1994, the MRFSS obtained 276 interviews from charterboat anglers aboard 33 boats that were identified. These boats represented $22 \%$ of the active fleet identified through the MRD permit file. Area distribution was as follows, in percent of boats by county:

|  | Beaufort | Charleston | Georgetown | Horry |
| :--- | :---: | :---: | :---: | :---: |
| MRFSS | 52 | 27 | 15 | 6 |
| MRD | 31 | 38 | 15 | 16 |

Distribution of effort as sampled in the MRFSS was as follows, in percent:

|  | Inland | Ocean $<3 \mathrm{mi}$. | Ocean $>3 \mathrm{mi}$. |
| :--- | :---: | :---: | :---: | :---: |
| MRFSS interviews | 28 | 17 | 54 |
| Estimated angler trips (MRFSS) | 23 | 22 | 55 |
| Reported angler trips (MRD) | 18 | 39 | 43 |
| Reported boat trips (MRD) | 21 | 21 | 58 |

This distribution suggested that the 1994 MRFSS somewhat overestimated the level of effort in the FCZ compared to that in waters under. state jurisdiction.

As in the two previous years, the MRFSS appeared to greatly overestimate the total number of angler trips, as follows:

|  | 1 | 2 | 3 | 4 | 5 | 6 | All |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| MRFSS | 0 | 0 | 30,270 | 0 | 25,639 | 0 | 55,909 |
| MRD | 106 | 2,326 | 7,606 | 10,999 | 4,199 | 939 | 26,175 |

The absence of effort for waves 2,4 , and 6 appeared to be attributable to sampling artifacts.

The NMFS apparently assumed a massive, sustained level of effort by virtually the entire fleet. This is in marked contrast to the largely casual, limited operations observed by creel clerks and reported by most marinas and booking agents. Rather than adhere to a regular sailing schedule, many boats operated on an opportunistic basis hardly compatible with the level of effort implied by the NMFS estimates.

Wave 3 provided a good example. The average effort of the 115 boats that reported making at least one trip was 15 trips/boat during the 61-day interval with an average of 4.5 anglers/trip. In order to achieve the NMFS effort estimate, these boats would have had to have made approximately 6,727 trips or 59 trips/boat. Thus,
each active vessel would have had to have made a trip on almost every day of the wave. This is highly improbable, since the weather during most of May was bad. Even if all permitted vessels (roughly 140) had fished, they would have had to have averaged 48 trips/boat. This is very unlikely given that < 10 boats reported operating at that level.

MRFSS interviews were obtained for 70 boat trips on 33 boats for which the vessel was identified. MRD trip reports were available for 52 (74\%) of these trips. Although some dates were not identical (+- two days), these trips were considered equivalent if the operator reported no other trips closer to the date indicated in the MRFSS interview. This approach was considered reasonable, since only a few trips fell into this classification and the boats involved made relatively few trips. For nine trips, the operators had submitted monthly reports that contained no trips close to the indicated date. For seven trips, operators had turned in reports indicating no activity for that month. No monthly report was received for the other two trips.

Individual trip comparison results are summarized below. N is the number of observations in each category. Comparable hours fished was +- 0.5 hour. Comparable numbers of fish caught were +$10 \%$. Species composition was considered comparable in the species listed accounted for at least two-thirds of the overall catch.

The usual difference in the number of anglers was +- one. The anglers interviewed typically overestimated the amount of time actually spent fishing by including running time. There was a high level of agreement on target species, since relatively few were involved and many trips were non-specific (i.e., the target was "any"). Comparability of catch information varied greatly depending on the variety and number of fish caught and the amount of fish released (for which identities and numbers could not be verified during the interviews). Agreement between interview data and trip report information was uniformly better than in previous years.

Aggregate results of these comparisons are shown in Table I-1. The percentages shown were calculated as [(MRFSS-MRD)/(MRD] $\times 100$. There was close agreement in the total number of anglers, as in

Table I-1. Comparison of the 1994 MRFSS interview data and MRD report information for specific trips.

| Category | MRFSS | MRD | 1992 | difference |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | 1993 | 1994 |
| Number of anglers | 221 | 226 | $+2$ | - 12 | - 2 |
| Hours fished | 221.0 | 188.5 | $+54$ | + 63 | $+17$ |
| Number of fish caught: |  |  |  |  |  |
| Oceanic pelagics |  |  |  |  |  |
| Dolphin | 16 | 19 | $+25$ | - 6 | - 16 |
| Wahoo | 4 | 4 | 0 | 0 | 0 |

| Sharks | 47 | 53 | - 50 | - 14 | - 11 |

previous years. Effort (hours fished) was overestimated by the fishermen interviewed. The extent of agreement for numbers of fish caught varied greatly with few trends apparent over the three-year data set.

In terms of reliability, each data source had probable error elements. Many anglers were tired and/or somewhat inebriated when interviewed in the MRFSS. Most were out of state residents with little local fishing experience or knowledge of fish identity. If significant numbers of fish had been released, the anglers often couldn't recall well their number or identity.

Trip reports submitted to the MRD often were completed by boat operators (or their agents) at the end of the month from notes in their logs. There often was some confusion over exact dates, particularly if a boat had made many trips (although this would not have been a factor in wave totals).

Verification is frequently cited by the NMFS as justification for their procedures. The MRD trip reports were not verified and all information was accepted as submitted. The NMFS verification procedure, however, simply validated the fact that an individual was interviewed. It couldn't substantiate what species were caught or how many of each, only the angler's opinion. In this respect, the validity of the data obtained in the MRFSS was no better established than that of the information submitted on trip reports.

The estimated total charterboat catches based on MRFSS data and MRD trip reports are compared in Table I-2. Only estimates for waves 3 and 5 were included in the MRFSS figures, which simply enhances the conclusion that the NMFS catch estimates were greatly exaggerated.

This document was printed at a total cost of $\$ 176.13$. A total of 100 copies was printed at a cost of $\$ 1.76$ per copy.

Table I-2. Charterboat catch estimates (in numbers of fish) from the MRFSS and MRD trip reports. NR - None Reported.
